Abstract: High-spin level structure of the neutron-rich nucleus $^{91}\text{Y}$ has been reinvestigated via the $^{82}\text{Se}(^{13}\text{C}, \text{p3n})^{91}\text{Y}$ reaction. A newly constructed level scheme including several key levels clarifies the uncertainties in the earlier studies. These levels are characterized by the breaking of the $Z = 38$ and $N = 56$ subshell closures, which involves in tensor force and the spin-isospin dependent central force.

Key words: neutron-rich nucleus; level scheme; tensor force; spin-isospin dependent central force

CLC number: O571.21; Document code: A DOI: 10.11804/NuclPhysRev.32.04.375

1 Introduction

It is well known that the high-spin states of near-spherical nuclei can be constructed by the aligned angular momentum of open shell nucleons. The maximum spin occurs at the configuration termination in the valence space. To generate higher-spin states, the shell closure should be broken. A number of studies have revealed such excitation process for nuclei around the quasidoubly magic nucleus $^{88}\text{Sr}$.

The low-lying levels of nuclei with $38 < Z < 50$ and $50 < N < 56$ are dominated by the valence-nucleon excitations within the $\pi(p_{1/2}, g_{9/2})$ and $\nu d_{5/2}$ shell-model orbitals. The medium- or high-spin levels can be understood as the particle-hole excitations. Federman et al. [5-6] have theoretically studied the proton $p_{3/2} \rightarrow p_{1/2}$ and neutron $d_{5/2} \rightarrow g_{7/2}$ excitations and given the reasonable explanations for the reductions of the $Z = 38$ and $N = 56$ energy gaps. The proton-neutron interaction includes tensor force and the spin-isospin dependent central force$^{[7-8]}$. In the picture of tensor force$^{[7]}$, the enhanced $\pi p_{1/2} - \nu d_{5/2}$ and reduced $\pi p_{3/2} - \nu d_{5/2}$ monopole interaction may arise from the tensor component if the others contribute the same intertional values. Hence, when the $\nu d_{5/2}$ orbital is occupied by more neutrons, the $\pi p_{1/2}$ orbital goes down while $\pi p_{3/2}$ orbital comes up, that is, the $Z = 38$ energy gap becomes smaller. Likewise, the reduction of the $N = 56$ gap can be associated with the spin-orbital partners $\pi g_{9/2}$ and $\nu g_{7/2}^{[6]}$, between which the interaction is the so-called spin-isospin dependent central force$^{[8]}$.

The production of neutron-rich nucleus $^{91}\text{Y}$ is problematic via the conventional (HI, zn) reaction. High-spin states of $^{91}\text{Y}$ have been initially investigated via fusion-evaporation reaction $^{82}\text{Se}(^{12}\text{C}, p2n)^{91}\text{Y}^{[9]}$. It was not until recently that an extended level scheme is constructed by means of the fission of $^{221}\text{Pa}$ produced by a $^{24}\text{Mg}$ beam impinging on a $^{173}\text{Yb}$ target$^{[10]}$. In this work, the high-spin level structure is reinvestigated and the configurations are figured out, in analogy to our earlier study of the $N = 52$ isotone $^{92}\text{Zr}^{[11]}$.

2 Experiment

High-spin states of $^{91}\text{Y}$ were populated through the $^{82}\text{Se}(^{13}\text{C}, \text{p3n})^{91}\text{Y}$ reaction. The $^{13}\text{C}$ beam was provided by the HI-13 Tandem Accelerator of the China Institute of Atomic Energy (CIAE), and the target was $2.11 \text{mg/cm}^2$ isotopically enriched $^{82}\text{Se}$ on 8.56

1 Introduction

It is well known that the high-spin states of near-spherical nuclei can be constructed by the aligned angular momentum of open shell nucleons. The maximum spin occurs at the configuration termination in the valence space. To generate higher-spin states, the shell closure should be broken. A number of studies have revealed such excitation process for nuclei around the quasidoubly magic nucleus $^{88}\text{Sr}$.

The low-lying levels of nuclei with $38 < Z < 50$ and $50 < N < 56$ are dominated by the valence-nucleon excitations within the $\pi(p_{1/2}, g_{9/2})$ and $\nu d_{5/2}$ shell-model orbitals. The medium- or high-spin levels can be understood as the particle-hole excitations. Federman et al. [5-6] have theoretically studied the proton $p_{3/2} \rightarrow p_{1/2}$ and neutron $d_{5/2} \rightarrow g_{7/2}$ excitations and given the reasonable explanations for the reductions of the $Z = 38$ and $N = 56$ energy gaps. The proton-neutron interaction includes tensor force and the spin-isospin dependent central force$^{[7-8]}$. In the picture of tensor force$^{[7]}$, the enhanced $\pi p_{1/2} - \nu d_{5/2}$ and reduced $\pi p_{3/2} - \nu d_{5/2}$ monopole interaction may arise from the tensor component if the others contribute the same intertional values. Hence, when the $\nu d_{5/2}$ orbital is occupied by more neutrons, the $\pi p_{1/2}$ orbital goes down while $\pi p_{3/2}$ orbital comes up, that is, the $Z = 38$ energy gap becomes smaller. Likewise, the reduction of the $N = 56$ gap can be associated with the spin-orbital partners $\pi g_{9/2}$ and $\nu g_{7/2}^{[6]}$, between which the interaction is the so-called spin-isospin dependent central force$^{[8]}$.

The production of neutron-rich nucleus $^{91}\text{Y}$ is problematic via the conventional (HI, zn) reaction. High-spin states of $^{91}\text{Y}$ have been initially investigated via fusion-evaporation reaction $^{82}\text{Se}(^{12}\text{C}, p2n)^{91}\text{Y}^{[9]}$. It was not until recently that an extended level scheme is constructed by means of the fission of $^{221}\text{Pa}$ produced by a $^{24}\text{Mg}$ beam impinging on a $^{173}\text{Yb}$ target$^{[10]}$. In this work, the high-spin level structure is reinvestigated and the configurations are figured out, in analogy to our earlier study of the $N = 52$ isotone $^{92}\text{Zr}^{[11]}$.

2 Experiment

High-spin states of $^{91}\text{Y}$ were populated through the $^{82}\text{Se}(^{13}\text{C}, \text{p3n})^{91}\text{Y}$ reaction. The $^{13}\text{C}$ beam was provided by the HI-13 Tandem Accelerator of the China Institute of Atomic Energy (CIAE), and the target was $2.11 \text{mg/cm}^2$ isotopically enriched $^{82}\text{Se}$ on 8.56
mg/cm² natural lead backing. The emitted γ rays from the reaction products were detected by an array consisting of 2 planar and 12 Compton-suppressed HPGe detectors. The energy and efficiency calibrations were made using the $^{60}$Co, $^{133}$Ba, and $^{152}$Eu standard sources and the typical energy resolution was 2.0~2.5 keV at full width at half-maximum (FWHM) for the 1332.5- keV γ ray of $^{60}$Co. Events were collected when at least 2 detectors were fired within the prompt 80 ns coincidence time window. Under these conditions, a total of $2.5 \times 10^7$ coincidence events were recorded and the data was sorted into a symmetrized $E_\gamma$-$E_\gamma$ matrix for subsequent off-line analysis.

In order to obtain multipolarity information of the emitted γ rays, two asymmetric coincidence matrices were constructed using the γ rays detected at all angles (as y axis) against those observed at $\sim 34^\circ$ (or $\sim 146^\circ$) and 90° angles (as x axis) respectively. The ADO ($\gamma$ ray angular distribution from oriented nuclei) ratio $^{[12]}$ is defined as $R_{ADO}(\gamma) = \frac{I_y(34^\circ)}{I_y(90^\circ)} = \frac{N_y(34^\circ)}{N_y(90^\circ)}$ (here $\gamma$ refers to a particular energy value.). By setting gates on the $y$-axis with all the detectors, the γ ray intensities $I_y(34^\circ)$ and $I_y(90^\circ)$ were extracted from the coincidence spectra regardless of the multipole character of the gating transition. Generally, one transition is adopted as stretched quadrupole transition if its $R_{ADO}(\gamma)$ is significantly larger than 1.0 or adopted as dipole transition if its $R_{ADO}(\gamma)$ is less than 1.0.

3 Experimental results

We have noticed a significant difference between the level schemes given in the earlier studies$^{[9-10]}$. To the extent of our knowledge, it is difficult to understand the identified strong γ rays in Ref. [10] not listed in Ref. [9]. In order to clarify the uncertainties, we have carefully checked the γ-γ coincidence relationships and construct a new level scheme shown in Fig. 1. Except for 3569.1-, 5579.9-, 7581.2- keV levels and 1411.9-, 953.5-, 1297.8- keV γ rays (see Fig. 2 for γ-γ coincidence relationships), the other levels and γ rays in Ref. [10] can not be confirmed in the present work. It is worth pointing out that the 766.8- and 579.3- keV γ rays are weak in Fig. 2 but can be confirmed in coincidence with the 672.3-, 335.0- and 327.7- keV lines.

On referring to the prior studies$^{[9-10]}$, an obvious contribution of our work is the revisional or tentative assignment of the spin-parity values of the 3734.4-, 4483.4- and 4811.1- keV levels. According to the ADO ratios of γ rays listed in Table 1, the 1577.0- keV γ ray is a quadrupole transition and the spin of the 3734.4- keV level is therefore (21/2). Accepting the spins and parities of 3528.4- and 4148.4- keV levels in Ref. [9], the intensity ratio between the 415.3- and 619.6- keV lines proposes that the former is an electric quadrupole(E2) rather than magnetic quadrupole(M2) transition and the parity of the 3734.4- keV level is therefore positive. It can be seen from Fig. 3 that the 327.7- and 335- keV lines are obviously dipole transitions if the 619.6-, 929.5-, 1371.0- and 1577.0- keV lines are quadrupole ones. Hence, the 4483.4- keV level is (27/2). Considering the intensity ratio of the 335.0- and 953.5- keV γ rays, the 953.5- keV γ ray should be an E3 rather than M3 transition and the parity of the 4483.4- keV level is of course negative. (29/2) is tentatively adopted for the 4811.1- keV level according to the dipole character of the 327.7- keV line.
therefore arise from the competition of one proton and two neutrons in pair. It is expected that the (13/2+) level above the 9/2+ can be associated with the πg9/2 ⊗ ν(d5/2) configuration. The three-particle πg9/2 ⊗ νd5/2 configuration may persist till the (17/2+). The (17/2+) is the maximum spin for the termination of the configuration in the space π(p1/2; g9/2) and νd5/2.

Above the fully aligned (17/2+), the states should therefore arise from the competition of one proton and one neutron excitations across the respective Z = 38, N = 56 subshell closures. It has been pointed out in our previous results[11] that the low-energy one is attributed to the neutron excitation. In the same way, we propose that the excitation from the 2157.4 keV (17/2+) to 3528.4 keV (21/2+) level is ν(d5/2 → g7/2) and the 3528.4 keV state has the πg9/2 ⊗ ν(d5/2g7/2) configuration. The νg7/2 single-particle excitation energy relative to the νd5/2 decreases from ~2.19 MeV in 91Zr to ~0.17 MeV in 101Sn[13], namely ~0.2 MeV lowered by adding a proton into the g9/2 orbital. The energy of the ν(d5/2 → g7/2) excitation in 92Zr (12+/14+ → (14+) is 1098.4 keV. Thus we can predict the excitation energy of the πg9/2 ⊗ νd5/2 → πg9/2 ⊗ ν(d5/2g7/2) in 91Y to be ~1298.4(=1098.4+200) keV.

Fig. 3 γ ray counts Nc(34°) and Na(90°) of the two asymmetry matrices at 34° and 90° angles respectively gated on the 672 keV line. It’s very clear that the 327.7- and 335.0- keV γ rays are dipole transitions for their ADO ratios are smaller than 1.0 while the 619.6-, 929.5-, 1371.0- and 1577.0- keV lines are quadrupole transitions for their ADO ratios are larger than 1.0.

### Discussion

Since the Fermi levels of 91Y lie at the πp1/2 and νd5/2, the active proton and neutron orbitals are (f5/2,p3/2,p1/2,g9/2) and (d5/2,s1/2,d3/2,g7/2,h11/2), respectively (for the single-particle energies see Ref. [11]). The 9/2+ state is naturally the g9/2 proton coupled with two d5/2 neutrons in pair. It is expected that the (13/2+) level above the 9/2+ can be associated with the πg9/2 ⊗ ν(d5/2) configuration. The three-particle πg9/2 ⊗ νd5/2 configuration may persist till the (17/2+).
This indicates a possible reduction of the energy gap well with this value. The lowered +
strated by the excitation energy of the 2
the introduction part, the reduction may be associated with the proton-neutron tensor force[8]. To
generate the (25/2) spin value, both of the Z = 38 and N = 56 subshell closures should be broken. Therefore,
the (25/2) state is proposed for the (25/2) state.
For achieving higher-spin state, the proton should be further excited to the g9/2, namely π(p3/2/f5/2 →
g9/2). The (27/2−) and (29/2−) states appear to be associated with the π(p3/2/g5/2) ⊗ ν(d5/2/g7/2) and
π(f5/2/g9/2) ⊗ ν(d5/2/g7/2) configurations, respectively.

5 Summary

The high-spin level structure of 91Y has been re-investigated through the 82Se(13C, p3n)91Y fusion-
evaporation reaction. The level scheme has been modified. The spin-parity values of states in 91Y above
the fully aligned (17/2+) state have been proposed. The configuration of high-spin states above the fully
aligned (17/2+) state are figured out in terms of the breaking of the Z = 38 and N = 56 subshell closures.
The tensor force and spin-isospin dependent central force play an important role in breaking the subshells.
