Abstract We discuss modeling of nuclear structure beyond the 2-body interaction paradigm. Our first example is related to the need of three nucleon contact interaction terms suggested by chiral perturbation theory. The relationship of the two low-energy effective coupling parameters for the relevant three nucleon contact interaction terms c_D and c_E that reproduce the binding energy of ³H and ³He has been emphasized and the physically relevant parameter region has been illustrated using the binding energy of ⁴He. Further justification of A-body interaction terms is outlined based on the Okubo-Lee-Suzuki effective interaction method used in solving the nuclear many-body problem within a finite model space. The third example we use is an exactly solvable A-body extended paring interaction applied to heavy nuclei with a long isotopic chain; in particular using ¹³²Sn as closed core system illustrates a remarkable relationship between the extended pairing strength G(A) and the size of the valence space dim(A) for the members of the Sn-isotope chain: $G(A) = \alpha \dim(A)^{-\beta}$ with $\alpha = 259.436$ and $\beta = 0.9985$ which is actually a one parameter expression since β is practically 1. These three cases present evidence for the need of better understanding of the NNN-, NNNN-, and A-body interactions in nuclei either derived from ChPT or from a phenomenological considerations.

Key words: nuclear interaction; A-body interaction; exactly solvable model CLC number: 0571.6 Document code: A DOI: 10.11804/NuclPhysRev.34.01.105

1 Introduction

The high precision, QCD derived, nucleon interaction that describes the NN-scattering phase shifts and the deuteron, when applied to the light s- and pshell nuclei points to the necessity of NNN-interaction terms^[1, 2]. Thus, the conventional two-body interaction paradigm is challenged and the need of 3-body and possibly A-body interaction define a new research frontier. The structure of the three-body terms has been studied previously using the meson exchange theory^[3]. However, with the advance of the Chiral Perturbation Theory (ChPT)^[4, 5] the structure of the three-body interaction has been clearly identified and well justified via QCD.

Higher many-body interaction terms (e.g. NNNNinteraction terms) are also part of the interaction as derived from QCD via $ChPT^{[6]}$. The Okubo-Lee-Suzuki (OLS) effective interaction method, employed in solving the nuclear many-body theory, also introduces interaction terms beyond the common 2-body interaction^[7, 8]. All this seems to be pointing to the need of A-body interactions for the description of the nuclear structure. It also raises the question about the importance of the A-body interactions in very heavy nuclei. Fortunately, there is an exactly solvable A-body model - the extended pairing model - that is applicable as an A-body interaction to very heavy nuclei; therefore, it can help to address this question^[9-11].

In the next section we briefly discuss the microscopic nuclear physics hamiltonian; the types of the high-precision NN-interaction potentials and their failure to properly account for the structure of the nuclei with more than two nucleons. In Sec. 3 we discuss the values of the $c_{\rm D}$ and $c_{\rm E}$ parameters of the NNNintercation^[2] and their physically acceptable regions as deduced from the binding energy of ³H, ³He, and ⁴He. In Sec. 4 we further extend our argument for A-body nuclear interactions by using the modern OLS effective interaction in finite model space method. In Sec. 5 we briefly discuss the results of applying the A-body Extended Pairing Interaction (EPI) to few long isotope

chains like Sn and Pb nuclei. Last section is our conclusion about the needs of the future nuclear structure modeling based on A-body nuclear interactions.

2 Modeling the nuclear interactions

Unlike the electromagnetic and the gravitational interaction, the mathematical form of the nuclear interaction has been very elusive. This is due to the fact that the nuclear interaction arises non-trivially from the quark structure of the nucleons and thus related to the theory of the QCD. Never the less, the field of nuclear structure modeling has advanced significantly, based on general quantum mechanical principals and techniques. In particular, the microscopic approach has been very successful especially with the advance of computational techniques and computer power that have allowed for the construction of effective high-precision meson and/or QCD derived NNpotentials. The free parameters of the high-precision NN-potentials are usually fixed by the experimental two-nucleon scattering data and describe the 2-body system extremely well^[12]. Unfortunately, these potentials produce unsatisfactory description of the 3- and 4-body systems^[13].</sup>

A nuclear many-body system near equilibrium can be viewed as subject to a mean-field Harmonic Oscillator (HO) potential. It is well-known that one can understand the magic numbers and the shell structure of nuclei within the 3-dimensional HO approximation plus a spin-orbit potential^[14]. Using the HO singleparticle states one can write a general Hamiltonian with one- and two-body terms. Despite the significant symmetry relations, due to rotational symmetry and due to the fermion exchange properties and the hermition requirement on the energy operator, the number of independent phenomenological parameters is often more than a dozen - usually it is of order of few hundred for the valence NN interaction alone. The independent parameters of the interaction are often fitted to experimental data by starting with some initial values that come from a relevant theory or model.

Many of the high-precision NN-potentials, commonly used to build the microscopic interactions for multi-nucleon systems, have very complicated but methodically developed structure in terms of spin, isospin, and angular momentum components although sometimes there is a very complicated radial dependence. For example, the Argonne V18 potential has 18 different terms^[15]. Other potentials use non-local terms like CD-Bonn^[16] and Nijmegen^[17]. However, when applied to A > 2 systems all of these potentials have a serious difficulties that were eventually overcome by using three-body interactions^[4, 13, 18].

By the end of the twentieth century it become clear that a two-body interaction by itself is inadequate - even for the description of the lightest nuclei 2 < A < 5. Comparative studies of various potentials, such as AV18, Nijmegen, CD-Bonn, and N³LO, with or without three body terms have demonstrated the inadequacy of the pure two-body interactions and the need for three-body interaction terms^[12, 13]. For example, all these interactions (AV18, Nijmegen, CD-Bonn, and N³LO) describe very well the deuteron properties such as binding energy, radius, and quadruple moment but fail by more than 0.5 MeV to reproduce the binding energy of triton^[12] and underbind ⁴He by more than 4 MeV^[13].

Although the meson-exchange approach was successful, it was clear that this phenomenological models should be derived from the underling QCD. Thus the ChPT approach became a prominent technique that produced the high-precision NN-potential $N^{3}LO$ and then guided the researchers into the structure of the NNN- and NNNN-interactions^[6, 12, 19].

3 The NNN-body interaction

The use of the ChPT in the derivation of the nucleon interactions from QCD helped in identifying the mathematical form of various interaction terms along with the relevant parameters. Unfortunately, parameters related to contact terms in the interaction could not be determined. Thus, the strengths, $c_{\rm D}$ and $c_{\rm E}$, of the two-nucleon contact interaction with one-pion exchange to a third nucleon and the three-nucleon contact interaction are identified as undetermined parameters in the effective ChPT interaction^[1]. As such they need to be fixed by comparison with experiment.

The values of the parameters $c_{\rm D}$ and $c_{\rm E}$ that reproduce the binding energy of ³H and ³He within 0.5 keV of the experimental values correspond to two nonintersecting curves in the $c_{\rm D}$ and $c_{\rm E}$ plain as seen from Fig. 1. In order to further narrow down the range of $c_{\rm D}$ values one considers the averaged $c_{\rm D}-c_{\rm E}$ curve and evaluates the binding energy of the ⁴He system that results in two possible physical regions denoted by A and B; where region A corresponds to $c_{\rm D}$ of order 1 and region B for $c_{\rm D}$ of order 10. Finally, the charge radius of ⁴He points to the region A as the reasonable range of values for the $c_{\rm D}$ parameter while the $c_{\rm E}$ parameter is determined by the averaged $c_{\rm D} - c_{\rm E}$ curve^[2].

Conceptually, there are three important concerns: First, the ChPT NN-potential was one order higher than the NNN-potential and no NNNN-potential was

Fig. 1 (color online) Relations between $c_{\rm D}$ and $c_{\rm E}$ for which the binding energy of ³H (8.482 MeV) and ³He (7.718 MeV) are reproduced. (a) ⁴He groundstate energy along the averaged $c_{\rm D}-c_{\rm E}$ curve. The experimental ⁴He binding energy (28.296 MeV) is reproduced to within 0.5 MeV over the entire range depicted. (b) ⁴He charge radius r_c along the averaged $c_{\rm D}-c_{\rm E}$ curve. Dotted lines represent the r_c uncertainty due to the uncertainties in the proton charge radius.

included. That is, the high-precision NN-potential was N³LO (next-to-next-to-leading order)^[12] while the ChPT NNN-potential was at the N²LO order^[19] and the NNNN-potential^[6] was not yet readily available. The second concern is that the range of the 3-body interaction parameter $c_{\rm D}$ is determined by the properties of the 4-body system ⁴He; this, however, was resolved by a later study that used the β^- decay of ³H into ³He and confirmed the physically relevant region A for the parameter $c_{\rm D}^{[20]}$. The third concern is related to the fact that these are high-precision studies and at this level of accuracy the difference between the proton and nucleon mass could be important for the A=3 systems^[21].

4 Effective A-body interactions

In the previous section we discussed results obtained by using QCD derived interactions and the role of the NNN-interaction in the description of the light nuclei. Clearly 3- and 4-body interaction terms are predictions of the ChPT. Thus A-body interactions can be viewed as real physical interactions within the ChPT approach to nuclei. However, there is another way to arrive at A-body interactions that are phenomenological effective interactions since they are related to our inability to handle interacting systems in infinite Hilbert spaces^[22]. Since the quality of a model is judged by its ability to reproduce the experimental data, as far as computational models are concerned, an A-body interaction which gives results that agree well with the experimental data is also a physically relevant interaction.

In practice, we are computationally limited to a finite subspace of the infinite Hilbert space of the full quantum many-body problem. The subspace that we can access is defined by finite set of computationally convenient many-body basis states. For a suitable choice of basis we hope to have good overlaps with low-lying physical states of the system under study. If we imagine the exact solutions are available for analysis and apply a unitary transformation to those eigenstates, we can produce a transformed set of solutions maximally overlapping with our chosen basis space.

For example, one may be interested in the lowest two energy states of a system, but would like to have some unitarily transformed version of these states that have maximal overlap with the two basis states that define a 2D computational space as shown in Fig. 2. By finding the relevant unitary transformation U, one can define an effective Hamiltonian that would have the lowest two states within the 2D space as desired. Then this effective Hamiltonian could be used in the calculations of more complicated multi-particle systems, *i.e.* one would find the unitarily transformed Hamiltonian that describes very well the low-energy states of a 2-body system in a mean field but within a Fock space that would be used later for an A-body system. Unfortunately, this transformation will turn any one- and two-body potential into a many-body effective interaction when applied to the relevant manybody system^[22].</sup>

Fig. 2 (color online) Geometrical interpretation of the Okubo-Lee-Suzuki transformation method for construction of effective Hamiltonian operators.

For A > 4, it seems impractical at present to obtain the structure of the A-body interactions as derived from ChPT as it was previously done for the NNN- and the NNNN-interaction terms. Before embarking on the extensive undertaking required for including higher-body effective interactions, it would be very helpful to investigate a simple exactly solvable Abody interaction model that has few parameters and is applicable to real A-body systems.

5 The Sn and Pb isotopes

It seems impractical at present to be able to obtain the structure of the A-body interactions from ChPT for A > 4. therefore, in order to determine the relevance of the A-body interactions one should use the general form of an A-body interaction and then to try to determine some of the A-body interaction strengths. For this reason, one needs simple exactly solvable Abody interaction with few parameters that can be adjusted to the experimental data. Fortunately, there is such an interaction - *the Extended Pairing Interaction* (EPI)^[9]. This exactly solvable model is similar to the two-body proton-neutron pairing which was shown to be exactly solvable as well^[23].

Fig. 3 (color online) The solid blue line gives the theoretical RBE for the Sn isotopes relative to the ¹³²Sn nucleus. The insets show the fit to the values of G that reproduce exactly the experimental data using ¹³²Sn core. The lower inset shows the two second order polynomial fitting $\ln(G(A)) =$ $365.0584 - 6.4836 A + 0.0284 A^2$ for even values of A and $\ln(G(A)) = 398.2277 - 7.0349 A + 0.0307 A^2$ for odd values of A. The upper inset shows a fit to G(A) that is inversely proportional to the size of the model space, (dim(A)), that is valid for even as well as odd values of A: $G(A) = \alpha \dim(A)^{-\beta}$ with $\alpha = 259.436$ and $\beta = 0.9985$. The Nilsson BE energy is the lowest energy of the non-interacting system.

Deformation is common in very heavy nuclei and this often justifies the success and application of the Nilsson model. For the modeling purpose, one use deformation parameters from Ref. [24] and experimental binding energies from Ref. [25]. Theoretical relative binding energies (RBE) are calculated relative to a specific core: 132 Sn and 208 Pb for the cases considered. The RBE of the nucleus next to the core is used to determine an energy scale for the Nilsson single-particle/hole energies. For an even number of neutrons, one considers only pairs of particles. For an odd number of neutrons, one applies Pauli blocking to the Fermi level of the last unpaired fermion and consider the remaining fermions as if they are an even fermion system. The valence model-space consists of the neutron single-particle levels between two closed shells with magic numbers $50 \sim 82$ and $82 \sim 126$. By using the exact solvability of the model, values of Gare determined so that the experimental and theoretical RBE match exactly as seen in Fig. 3. The results are discussed in more details in Refs. [10, 11].

The Sn isotope chain is unique in the sense that there are two doubly magic members, the ¹⁰⁰Sn and ¹³²Sn. This allows us to use ¹³²Sn as zero RBE system with holes as it has been done for the Pb case^[11]. There is a very simple expression that works for even and odd systems simultaneously: $G(A) = \alpha \dim(A)^{-\beta}$; with $\alpha = 259.436$ and $\beta = 0.9985$ for ¹³²Sn core, while for ²⁰⁸Pb core case we have $\alpha = 366.7702$ and $\beta = 0.9972$. Having a one parameter expression (one practically has $\beta = 1$) for the extended pairing strength in such long chains of isotopes (~20 nuclei in a chain) is remarkable.

6 Conclusion

In this paper we have presented evidence for the need to better understanding of the NNN-, NNNN-, and A-body interactions in nuclei either derived from ChPT or from a phenomenological considerations. Therefore, one has to build A-body computational technology in the next generations of nuclear modeling codes. While the motivation for considering A-body interaction in the light-nuclei is strong as based on the ChPT QCD derived interactions, one is left to wonder if A-body interactions are also relevant to heavy nuclei. The results obtained with the help of the Extended Pairing Interaction, in particular the Sn and Pb isotopes discussed here seem to confirm the idea that A-body interactions are needed to understand better the binding energy of heavy nuclei. Often the imagination cannot capture all the possible implications and uses of an exactly solvable model. Beside the current applications of the EPI, one can also see that it would be a useful verification tool for A-body computational codes as well.

摘要: 讨论了核结构模型中两体以上相互作用的可能形式。首先以基于手征微扰论并适于描述轻核的三体接触型相 互作用为例,讨论了能合理描述³H和³He结合能的三核子接触型相互作用相关的两个低能有效耦合参数 $c_{\rm D}$ 和 $c_{\rm E}$ 间的关系并通过⁴He结合能给出了相应的物理参数区。其次通过Okubo-Lee-Suzuzki有效相互作用方法对核多体 问题在有限模型空间的求解,论证了A-体相互作用项。最后利用包含了A-体推广对力的可解模型对重核的同位 素长链进行了分析。以¹³²Sn为核芯,通过对Sn同位素链的计算揭示了推广对力参数G(A)与模型价核子空间维 数 dim(A)间的显著关系: G(A) = 259.436 dim(A)^{-0.9985}。这些分析结果说明,有必要对核中经手征微扰论或其它 唯象理论所得到的 NNN-, NNNN-,及A-体相互作用作进一步的研究。
